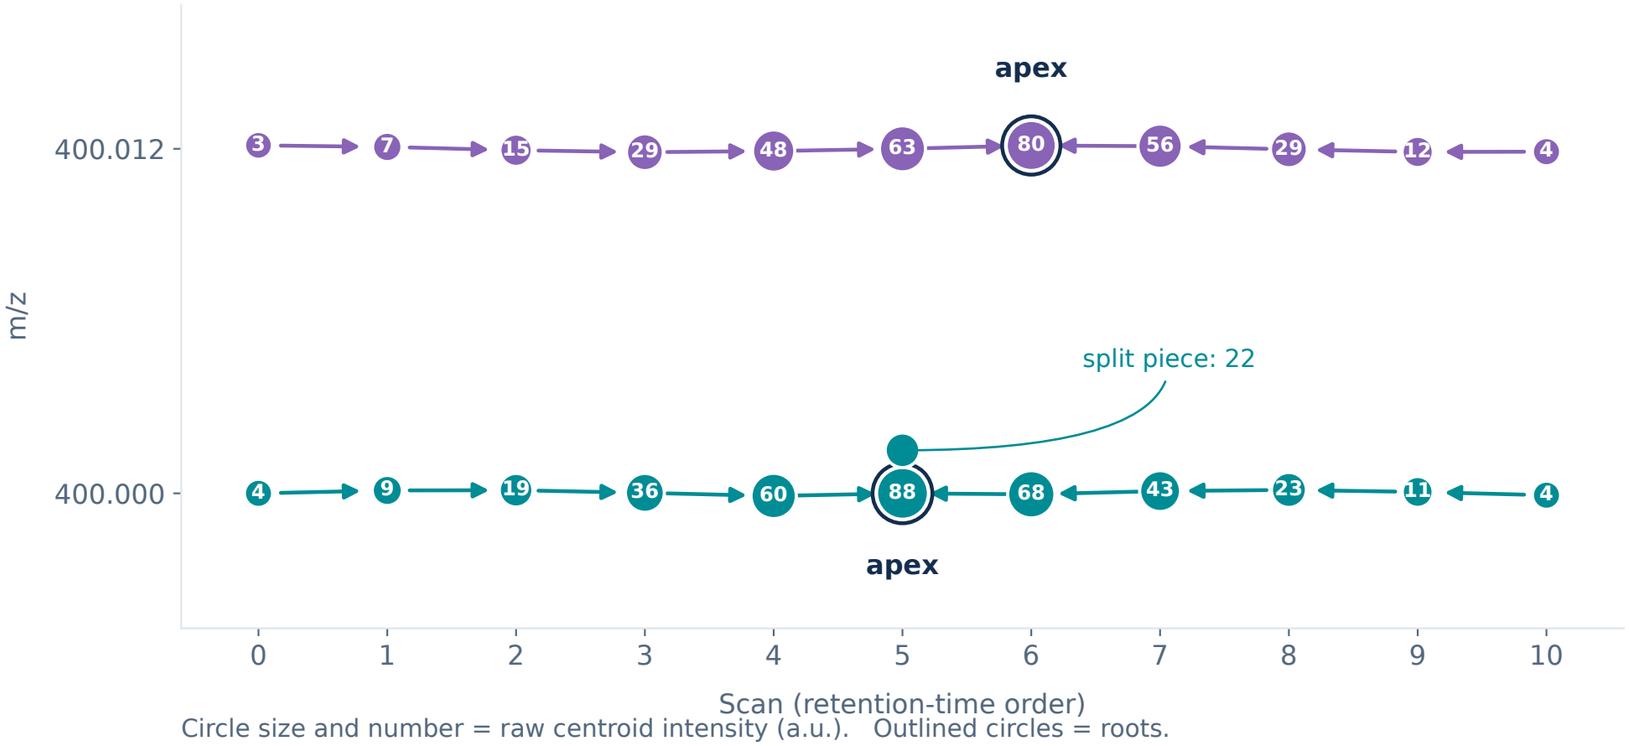
Each centroid follows a path to one apex

Arrows show the actual parent links. This is a top-down view of the point cloud.



Circle size and number = raw centroid intensity (a.u.). Outlined circles = roots.

01 Find eligible neighbours

Use the pair's m/z tolerance in nearby scans; link same-scan split centroids too.

02 Choose the highest neighbour

Move to a higher effective intensity.
If none is higher, this point is an apex.

03 Follow the arrows

All points reaching the same root belong to one initial basin.

Split example: 88 + 22 = 110
effective height; the stronger piece is the root.

A basin is the set of centroids whose uphill paths end at the same apex.
